Comprehensive Genomic Analysis Reveals Clinically Relevant Molecular Distinctions between Thymic Carcinomas and Thymomas

Nicolas Girard,¹ Ronglai Shen,² Tianhua Guo,³ Maureen F. Zakowski,³ Adriana Heguy,⁴ Gregory J. Riely,⁵ James Huang,⁶ Christopher Lau,¹ Alex E. Lash,⁷ Marc Ladanyi,^{1,3} Agnes Viale,⁸ Cristina R. Antonescu,³ William D. Travis,³ Valerie W. Rusch,⁶ Mark G. Kris,^{5,9} and William Pao^{1,5,9}

Abstract Purpose: Thymomas and thymic carcinomas are rare intrathoracic malignancies that can be invasive and refractory to conventional treatment. Because these tumors both originate from the thymus, they are often grouped together clinically. However, whether the underlying biology of these tumors warrants such clustering is unclear, and the optimum treatment of either entity is unknown.

Experimental Design: All thymic tumors were profiled for mutations in genes encoding components of the EGFR and KIT signaling pathways, assessed for EGFR and KIT expression by immunohistochemistry, and analyzed by array-based comparative genomic hybridization. Previously untreated tumors were subjected to global gene expression arrays.

Results: We analyzed 45 thymic tumors [thymoma, $n = 38$ (type A, $n = 8$; type B2, $n = 22$; type B3, $n = 8$); thymic carcinoma, $n = 7$]. One thymoma and one thymic carcinoma harbored *KRAS* mutations (G12A and G12V, respectively), and one thymoma had a G13V *HRAS* mutation. Three tumors displayed strong KIT staining. Two thymic carcinomas harbored somatic *KIT* mutations (V560del and H697Y). In cell viability assays, the V560del mutant was associated with similar sensitivities to imatinib and sunitinib, whereas the H697Y mutant displayed greater sensitivity to sunitinib. Genomic profiling revealed distinct differences between type A to B2 thymomas versus type B3 and thymic carcinomas. Moreover, array-based comparative genomic hybridization could readily distinguish squamous cell carcinomas of the thymus versus the lung, which can often present a diagnostic challenge.

Conclusions: Comprehensive genomic analysis suggests that thymic carcinomas are molecularly distinct from thymomas. These data have clinical, pathologic, and therapeutic implications for the treatment of thymic malignancies. (Clin Cancer Res 2009;15(22):6790-9)

Abstract

Histologic classification of thymomas has significant limitations with respect to both subtype definitions and consistency. In order to better understand the biology of the disease processes, we performed whole genome gene expression analysis. RNA was extracted from fresh frozen tumors from 34 patients with thymomas and followup data was available. Using the Illumina BeadStudio[®] platform and Human Ref-8 Beadchip, gene expression data was analyzed with Partek Genomics Suite[®], and Ingenuity Pathways Analysis (IPA). Unsupervised clustering of gene expression data, representing one of the largest series in literature, resulted in identification of four molecular clusters of tumors (C1–C4), which correlated with histology ($P=0.002$). However, neither histology nor clusters correlated with clinical outcomes. Correlation of gene expression data with clinical data showed that a number of genes were associated with either advanced stage at diagnosis or development of recurrence or metastases. The top pathways associated with metastases were amino acid metabolisms, biosynthesis of steroids and glycosphingolipids, cell cycle checkpoint proteins and Notch signaling. The differential expression of some of the top genes related to both metastases and stage was confirmed by RT-PCR in all cases of metastases and matched nonmetastatic cases. A number of potential candidates for therapeutics were also identified.

A Gene Signature to Determine Metastatic Behavior in Thymomas

Yasin Gokmen-Polar¹, Robert W. Coen^{2,3}, Chirya Parthi Dasgupta⁴, Jeff Williams⁵, Derek Mastaglio⁶, John F. Shore⁷, Kishan M. Chakraborty⁸, Ivan Yabuz Vidulich⁹, Kristen L. Shiver¹, Kenneth A. Keidar¹, Patrick A. Loehrer Sr¹, Sundeep Badve^{1,10}

Abstract
Thymoma represents one of the rarest of all malignancies. Stage and completeness of resection have been used to ascertain prognostic therapeutic strategy albeit with limited prognostic accuracy. A molecular classifier would be useful to improve the assessment of metastatic behavior and optimize patient management.

Methods: qRT-PCR assay for 23 genes (19 test and four reference genes) was performed on multi-institutional archival primary thymomas. The 23 gene expression levels were used to construct a signature, classifying tumors into Class 1 and 2, corresponding to low or high likelihood for metastasis. The signature was validated in an independent multi-institutional cohort of patients (n=75).

Results: A nine-gene signature that can predict metastatic behavior of thymomas was developed and validated using real-time RT-PCR analysis. In the training set, Class 1 and Class 2 thymomas had metastatic-free survival rates 77% and 20%, respectively (low risk) and high rates 27 risk of metastasis (P=0.0042, log-rank), respectively. For the validation set, 5-year metastasis-free survival rates 67% and 19% for predicted low- and high-risk patients (P=0.0006, log-rank), respectively. The 5-year metastasis-free survival rates for the validation set were 49% and 47% for Class 1 and 2, respectively (P=0.0017, log-rank), respectively in univariate and multivariate Cox models including common prognostic factors for thymoma metastasis. The nine-gene signature was the only independent indicator of metastasis (P<0.05).

Conclusions: A nine-gene signature was established and validated which predicts the likelihood of metastasis more accurately than traditional staging. The latter underscores the histologic determination of the clinical course of thymoma and may improve patient management.

 Date Reported: 09/19/2012
 Treating Physician: Patrick Loehrer, M.D.
 Type of Specimen: FFPE (Frozen Tumor Tissue)

ASSAY DESCRIPTION
 DecisionDx-THYMOMA™ gene expression assay for thymoma tumors is a proprietary assay which uses RT-PCR to determine the expression levels of a 23 gene panel (of control) in primary tumor tissue samples. The DecisionDx-THYMOMA™ classification is calculated from the gene expression results as compared to results of a testing set of patients with known outcomes.

RESULTS
DecisionDx-Thymoma Class = 1

Patients with a Class 1 molecular signature have a low risk of experiencing near term (within 10 years) clinical metastasis

CLINICAL EXPERIENCE
 The DecisionDx-Thymoma assay has been evaluated in over 132 patients with thymoma to date. The majority of these patients participated in a prospective study using microarray-based analysis to define a molecular signature to establish the predictive accuracy of the gene expression profile. The most recent case date for this study is April 14, 2012. The outcome of metastasis has not yet occurred for Class 1 (low risk) and Class 2 (high risk) molecular signatures. The Kaplan-Meier survival time curves (Figure 1 and Table 1) below are based on the metastasis risk status as predicted by the DecisionDx-Thymoma gene expression profile. The available overall and Recurrence-Free Survival (RFS) values were calculated according to the DecisionDx-Thymoma gene expression profile (Fig 1, 2).

Figure 1: Kaplan-Meier plot of DecisionDx-Thymoma for Metastasis-Free Survival

Predicted Class	At 6 Years	At 10 Years
Class 1	93%	87% (95% CI)
Class 2	100%	100%

Log-rank test: p=0.0300
 ROC AUC: Sensitivity = 0.87
 Specificity = 0.90
 Negative Predictive Value = 87%

 The Gene Expression Profile Test for Thymoma

RAW DATA AND CALCULATION OF DECISIONDx-THYMOMA CLASS 1 AND 2
 DecisionDx-Thymoma™ assay uses RT-PCR to determine the expression levels of a 23 gene panel (of control) in primary thymoma tumor tissue. The control genes of thymoma are: POU2F1, POU2F3, POU2F10, GATA2, GATA3, GATA4, GATA5, GATA6, GATA7, GATA8, GATA9, GATA10, GATA11, GATA12, GATA13, GATA14, GATA15, and GATA16. The four control genes are: POU2F1, POU2F3, POU2F10, and POU2F11. The 23 gene panel consists of: GATA2, GATA3, GATA4, GATA5, GATA6, GATA7, GATA8, GATA9, GATA10, GATA11, GATA12, GATA13, GATA14, GATA15, GATA16, GATA17, GATA18, GATA19, GATA20, GATA21, GATA22, and GATA23. The 23 gene panel consists of: GATA2, GATA3, GATA4, GATA5, GATA6, GATA7, GATA8, GATA9, GATA10, GATA11, GATA12, GATA13, GATA14, GATA15, GATA16, GATA17, GATA18, GATA19, GATA20, GATA21, GATA22, and GATA23. The 23 gene panel consists of: GATA2, GATA3, GATA4, GATA5, GATA6, GATA7, GATA8, GATA9, GATA10, GATA11, GATA12, GATA13, GATA14, GATA15, GATA16, GATA17, GATA18, GATA19, GATA20, GATA21, GATA22, and GATA23.

ADDITIONAL BACKGROUND INFORMATION
 Comparison of the DecisionDx-Thymoma assay to the Memorial Sloan-Kettering system and other traditional prognostic factors. The validation study for the DecisionDx-Thymoma assay included a direct comparison to the Memorial Sloan-Kettering system and other traditional prognostic factors. The Memorial Sloan-Kettering system is commonly used in the U.S. and assigns stage based on the degree of tumor invasion and dissemination throughout the chest cavity and only (Fig 3, 4). Kaplan-Meier at risk metastasis has survival comparisons between the DecisionDx-Thymoma low and Memorial Sloan-Kettering low-recurrence stage (Fig 3) in thymoma stage (Fig 3) at 6 years and 10 years are shown in Table 2.

Table 2: Comparison of DecisionDx-Thymoma to Memorial Sloan-Kettering System

DecisionDx-Thymoma Class	Class	Metastasis Free Survival (MFS)		p-value
		All 6 years	All 10 years	
Low	Class 1	93%	87% (95% CI)	p=0.030
High	Class 2	100%	100%	p=0.000

Univariate analysis from the validation study confirms that the DecisionDx-Thymoma assay is an independent predictor of metastasis free survival (Table 3, Fig 5). Cox multivariate analysis was not performed due to the fact that the DecisionDx-Thymoma Class was the only statistically significant factor under univariate analysis.

Table 3: Univariate Analysis

Factor	Hazard Ratio	p-value
DecisionDx-Thymoma Class	3.34	<0.001
Memorial Sloan-Kettering Stage	2.49	<0.001
Class of Histology	1.52	<0.001
WHO malignant class	1.52	<0.001
Pathologic complete response	1.52	<0.001
Stage	1.52	<0.001
Age at 10 years	1.52	<0.001
Cox multivariate analysis (Low Hazard ratio = 0.001)	1.52	<0.001

Introduction

The Cancer Genome Atlas (TCGA) is an NIH initiative to create a comprehensive compendium of genomic alterations across 33 cancer lineages

The Thymic Epithelial Tumors (TET) project was the last project to be initiated by the TCGA as part of its rare tumor initiative

- The TCGA TET Analysis Working Group (AWG) is comprised of clinicians, scientists, and bioinformaticians tasked with the official analysis of the data.
 - 47 members from 24 institutions and 6 countries.

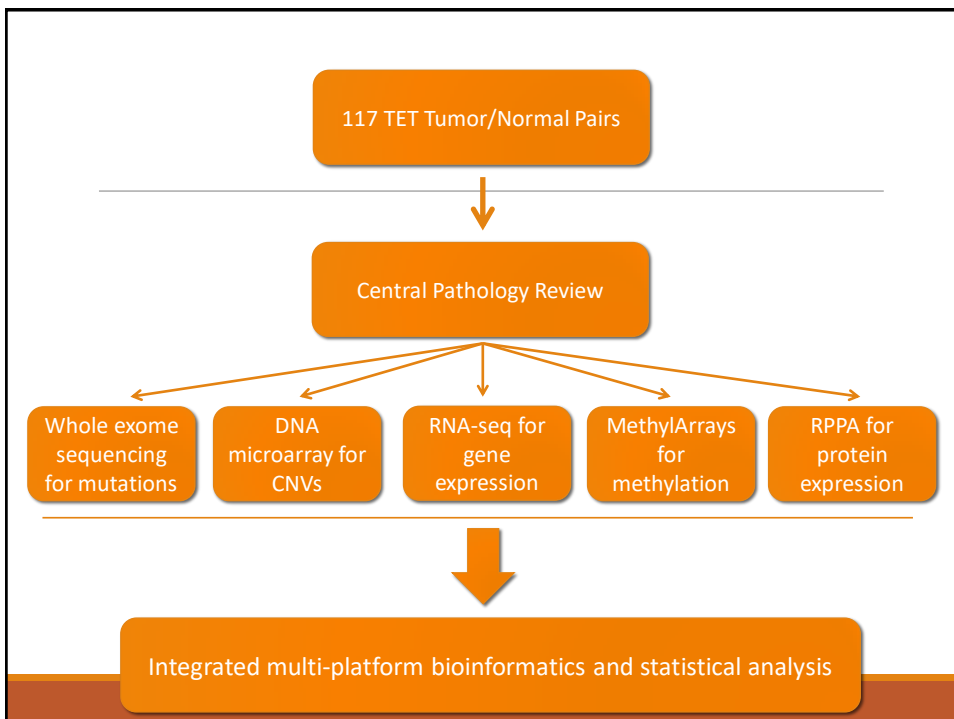

Tissue from **117 patients** were submitted to the TCGA from 18 institutions for comprehensive multi-omics analyses

Patient Demographics

Total number	117
Median age in years(range)	60 (17 – 84)
Male /Female	61 (52%)/56 (48%)
Race	
Caucasian	97 (83%)
Black	6 (5%)
Asian	12 (10%)
Data missing	2 (2%)
Masaoka stage	
I	36 (31%)
IIA	39 (33%)
IIB	19 (16%)
III	15 (13%)
IVA	1 (1%)
IVB	5 (4%)
Data missing	2 (2%)
Histologic subgroup:	
Type A	10 (9%)
Type AB	48 (41%)
Type B1	12 (10%)
Type B2	25 (21%)
Type B3	10 (9%)
Type TC	10 (9%)
Type MN-T	2(2%)

Clinical Characteristics

Adjuvant radiation therapy	39 (33%)
Adjuvant systemic therapy (total 14)	14 (12%)
Platinum- and/or anthracycline-containing combination	6
Other systemic therapy*	4
Targeted therapy*	2
Data missing	2
Autoimmune disease (total 39)*	39 (33%)
Myasthenia gravis only	32
Non-myasthenia gravis autoimmune disease only	7
Data missing**	6
Onset of myasthenia gravis (total 32)	32
Myasthenia gravis diagnosed prior to thymoma	20
Myasthenia gravis and thymoma diagnosed simultaneously	7
Myasthenia gravis diagnosed after thymoma	4
Data not available	1
Secondary malignancy (total 22)	
Diagnosed after thymic tumor	10
Diagnosed prior to thymic tumor	9
Diagnosed synchronously	3

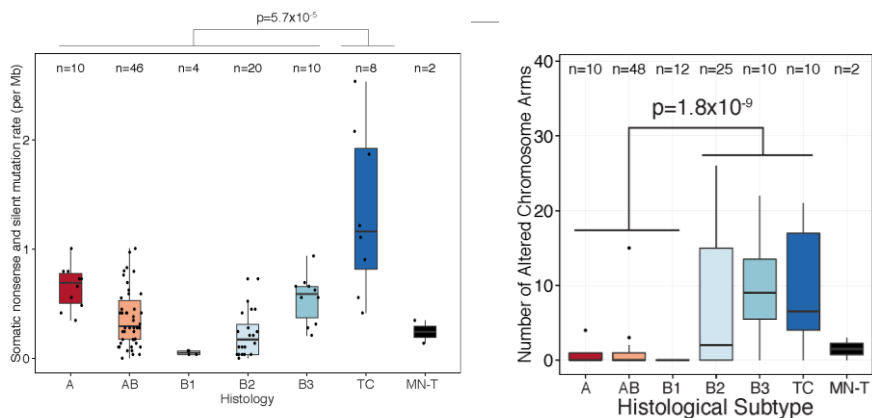

TETs have the lowest mutational burden among adult cancers

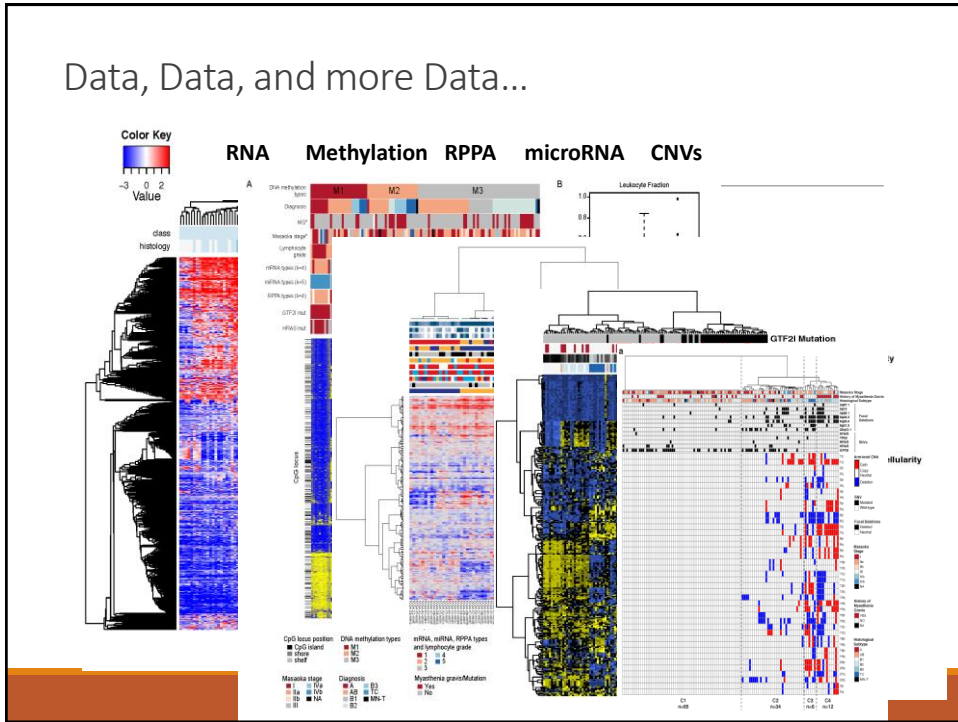

More aggressive WHO subtypes have a higher rate of somatic alterations

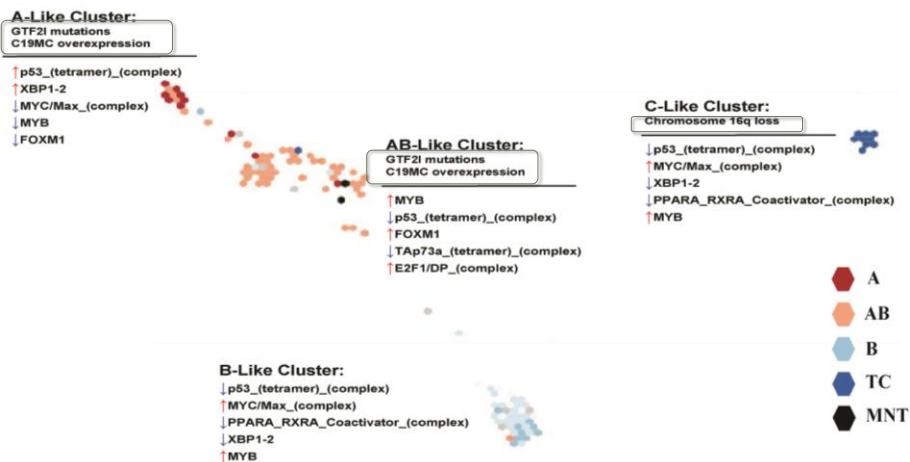

Thymic carcinomas have higher burden of point mutations and indels than thymoma

B2, B3, and TC tumors have higher number of altered chromosomal arms

Data, Data, and more Data...

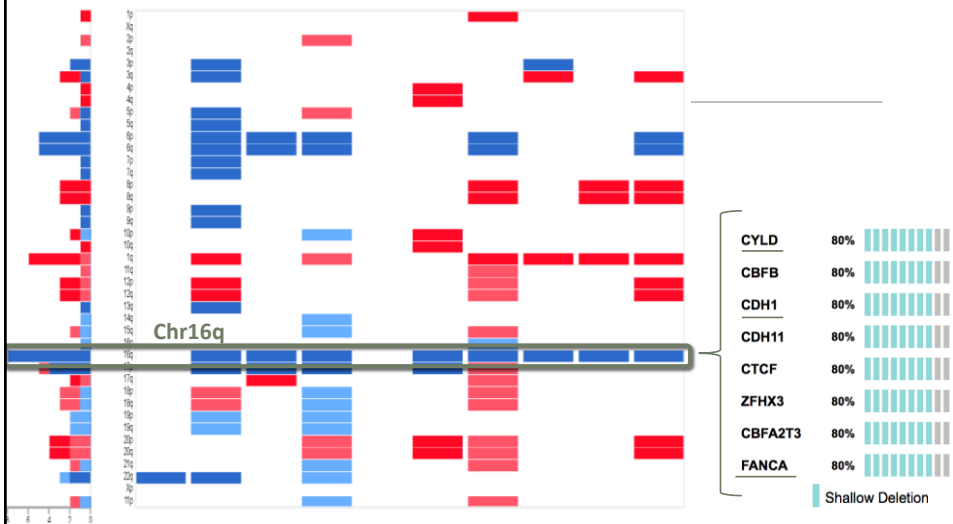

Multi-omics analyses identifies four molecular subtypes

Myasthenia gravis is associated with high tumoral overexpression of muscle auto-antigens and aneuploidy

Genomics of thymic carcinoma: Chromosome 16q loss

Tumor suppressors derived from the Sanger Cancer Gene Census

A novel case of an Microsatellite Instability (MSI)-high thymic carcinoma

- 78 year old female diagnosed with Stage IVb thymic carcinoma
- Overall survival: 12 months
- MSI-High, Chr 16q loss +
- Harbored a loss-of-function MLH1 E37* mutation with a concurrent 2.6-fold down-regulation in RNA expression

TCGA Summary

TETs have the lowest mutational burden among adult cancers, however, an enrichment of GTF2I, HRAS, NRAS, TP53, and loss of Chr16q (Type TC) is observed.

We identify four robust molecular subtypes of TETs with associated genomic hallmarks

Myasthenia gravis was linked to the over-expression of muscle auto-antigens and increased aneuploidy

We did not observe the presence of viruses (including polyoma) in TET tissues

We describe a novel case of microsatellite unstable thymic carcinoma - consideration of immune checkpoint therapy in this rare subset

Conclusions

Molecular analysis has some utility

Mutational profile identified

- GTF2i in A/AB
- No specific targets

RNA-based prognostic signature

- Validated in TCGA
- Limited commercial viability (rare tumors)
